

AI recall on unobserved cells rises with the amount of presence data

Recall on truth cells the model was NOT shown, pooled across $K=5$, $p=0.10$, $p=0.30$. NEAR = within 2 cells of an observation; FAR = beyond that (true extrapolation); ENS = any ensemble sample; dotted = random baseline. Recall above the baseline means the model predicts true locations; recall rising with data means it uses the records.
