

Does the AI predict true locations, and does it use the records well?

A. Recall vs number of observations

B. Recall vs percentage observed

Pooled over every species and world supplied ($K=5$, $p=0.10$, $p=0.30$ combined). FAR = recall on true cells more than two cells from any record (genuine extrapolation); NEAR = within two cells (local). Solid above its dashed baseline = better than chance; rising left-to-right = better with more records. Dotted vertical lines mark each regime's median.
